Global Wealth  
Databook 2016

## Preface

Since 2010, the Credit Suisse Wealth Report has been the leading reference on global household wealth. It contains the most comprehensive and up-to-date findings on global wealth across the entire wealth spectrum – from the very base of the "wealth pyramid," capturing 3.5 billion adults with wealth below USD 10,000, to those at the apex, who account for a small part of the world's population, yet own a significant share of its wealth.

Research for the Credit Suisse Global Wealth Databook was undertaken on behalf of the Credit Suisse Research Institute by Professors Anthony Shorrocks and Jim Davies, recognized authorities on this topic and the architects and principal authors of "Personal Wealth from a Global Perspective," (Oxford University Press, 2008). Rodrigo Lluberás was also a very significant contributor to the project.

The aim of the Credit Suisse Global Wealth project is to provide the best available estimates of the wealth holdings of households around the world, for the period since 2000. While the Credit Suisse Global Wealth Report highlights the main findings of our study, this Databook includes the full extent of our analysis. More importantly, it sets out in detail the data used in our Global Wealth project, the methodology for calculating estimates of wealth, and how this may differ from other reports in this field.

The Credit Suisse Global Wealth Databook provides detailed information on the evolution of household wealth levels during the period from 2000 to mid-2016, on both a regional and a country level. It presents our estimates on the distribution of wealth for over 200 countries. Based on this rich set of data, this year's Databook presents findings on the most significant trends at the bottom of the global wealth pyramid.

# 1. Estimating the pattern of global household wealth

## 1.1 Introduction

We aim to provide the best available estimates of the wealth holdings of households around the world for each year since 2000. More specifically, we are interested in the distribution within and across nations of individual net worth, defined as the marketable value of financial assets plus non-financial assets (principally housing and land) less debts. No country in the world has a single comprehensive source of information on personal wealth, and many low and middle income countries have little direct evidence of any kind. However a growing number of countries – including China and India as well many high income countries – have relevant data from a variety of different sources which we are able to exploit in order to achieve our objective.

The procedure involves three main steps, the first two of which mimic the structure followed by Davies et al (2008, 2011). The first step establishes the average level of wealth for each country. The best source of data for this purpose is household balance sheet (HBS) data, which are now provided by 48 countries, although 25 of these countries cover only financial assets and debts. An additional four countries have household survey data from which wealth levels can be calculated. Together these countries cover 65% of the global population and 95% of total global wealth. The results are supplemented by econometric techniques, which generate estimates of the level of wealth in 164 countries that lack direct information for one or more years.

The second step involves constructing the pattern of wealth holdings within nations. Direct data on the distribution of wealth are available for 33 countries. Inspection of data for these countries suggests a relationship between wealth distribution and income distribution, which can be exploited in order to provide a rough estimate of wealth distribution for 135 other countries, which have data on income distribution but not on wealth ownership.

It is well known that the traditional sources of wealth distribution data are unlikely to provide an accurate picture of wealth ownership in the top tail of the distribution for most countries. To overcome this deficiency, the third step makes use of the information in the rich lists published by Forbes Magazine and others to adjust the wealth distribution pattern in the highest wealth ranges.

Implementing these procedures leaves 50 countries for which it is difficult to estimate either the level of household wealth or the distribution of wealth, or both. Usually the countries concerned are small (e.g. Andorra, Bermuda, Guatemala, Monaco) or semi-detached from the global economy (e.g. Afghanistan, Cuba, North Korea). For our estimates of the pattern of global wealth, we assign these countries the average level and distribution of the region and income class to which they belong. This is done in preference to omitting the countries altogether, which would implicitly assume that their pattern of wealth holdings matches the world average. However, checks indicate that excluding these nations from the global picture makes little difference to the results.

Table 2-1 lists the 215 countries in the world along with some summary details. Note that China and India are treated as separate regions due to the size of their populations.

The following sections describe the estimation procedures in more detail. Two other general points should be mentioned at the outset. First, we use official exchange rates throughout to convert currencies to our standard measure of value, which is US dollars at the time in question. In international comparisons of consumption or income it is common to convert currencies using purchasing power parity (PPP) exchange rates, which take account of local prices, especially for non-traded services. However, in all countries a large share of personal wealth is owned by households in the top few percentiles of the distribution, who tend to be internationally mobile

and to move their assets across borders with significant frequency. For such people, the prevailing foreign currency rate is most relevant for international comparisons. So there is a stronger case for using official exchange rates in studies of global wealth.

The second issue concerns the appropriate unit of analysis. A case can be made for basing the analysis on households or families. However, personal assets and debts are typically owned (or owed) by named individuals, and may be retained by those individuals if they leave the family. Furthermore, even though some household assets, such as housing, provide communal benefits, it is unusual for household members to have an equal say in the management of assets, or to share equally in the proceeds if the asset is sold. Membership of households can be quite fluid (for example, with respect to older children living away from home) and the pattern of household structure varies markedly across countries. For all these reasons – plus the practical consideration that the number of households is unknown in most countries – we prefer to base our analysis on individuals rather than household or family units. More specifically, since children have little formal or actual wealth ownership, we focus on wealth ownership by adults, defined to be individuals aged 20 or above.

## 1.2 Household balance sheet data

The most reliable source of information on household wealth is household balance sheet (HBS) data. As shown in Table 1-1, “complete” financial and non-financial “real” balance sheet data are available for 23 countries for at least one year. These are predominantly high income countries, the exceptions being the Mexico and South Africa, which fall within the upper middle income category according to the World Bank. The data are described as complete if financial assets, liabilities and non-financial assets are all adequately covered. Another 25 countries have financial balance sheets, but no details of real assets. This group contains nine upper middle income countries and six lower middle income countries, and hence is less biased towards the rich world. The sources of these data are recorded in Table 1-2.

Europe and North America, and OECD countries in particular, are well represented among countries with HBS data, but coverage is sparse in Africa, Asia and Latin America. Fortunately survey evidence on wealth is available for the largest developing countries – China, India and Indonesia – which compensates to some extent for this deficiency. Although only financial HBS data are available for Russia, complete HBS data are available for the Czech Republic and financial data are recorded for nine other countries in Eastern Europe.

## 1.3 Household survey data

Information on assets and debts is collected in nationally representative surveys undertaken in an increasing number of countries (see Table 1-3 for the current list and sources.) For four countries this is the only data we have, and we use it to estimate wealth levels (with a correction for financial assets explained in the next section) as well as distributions. Data on wealth obtained from household surveys vary in quality, due to the sampling and non-sampling problems faced by all sample surveys. The high skewness of wealth distributions makes sampling error important. Non-sampling error is also a problem due to differential response rates – above some level wealthier households are less likely to participate – and under-reporting, especially of financial assets. Both of these problems make it difficult to obtain an accurate picture of the upper tail of the wealth distribution. To compensate, wealthier households are over-sampled in an increasing number of surveys, such as the US Survey of Consumer Finances and similar surveys in Canada, Germany, Spain, and several other EU countries. Over-sampling at the upper end is not routinely adopted by the developing countries which include asset information in their household surveys, but the response rates are much higher than in developed countries, and the sample sizes are large in China and India: 14,772 for the 2010 survey in China, and 105,800 for the 2012–2013 survey in India.

The US Survey of Consumer Finance is sufficiently well designed to capture most household wealth, but this is atypical. In particular, surveys usually yield lower totals for financial assets compared with HBS data. However, surveys usually do remarkably well for owner-occupied

housing, which is the main component of non-financial assets (see Davies and Shorrocks, 2000, p. 630). Our methodology recognizes the general under-reporting of financial assets in surveys and attempts to correct this deficiency.

Other features of the survey evidence from developing countries capture important real differences. Very high shares of non-financial wealth are found for the two low-income countries in our sample, India and Indonesia, reflecting both the importance of land and agricultural assets and the lack of financial development. On the other hand, the share of non-financial assets in China is relatively modest, in part because urban land is not privately owned. In addition, there has been rapid accumulation of financial assets by Chinese households in recent years. Debts are very low in India and Indonesia, again reflecting poorly developed financial markets.

For countries which have both HBS and survey data, we give priority to the HBS figures. The HBS estimates typically use a country's wealth survey results as one input, but also take account of other sources of information and should therefore dominate wealth survey estimates in quality. However, this does not ensure that HBS data are error-free.

## 1.4 Estimating the level and composition of wealth for other countries

For countries lacking direct data on wealth, we use standard econometric techniques to estimate per capita wealth levels from the 51 countries with HBS or survey data in at least one year. Data availability limits the number of countries that can be included in this procedure. However, we are able to employ a theoretically attractive model that yields observed or estimated wealth values for 173 countries, which collectively cover 97% of the world's population in 2016. There is a trade-off here between coverage and reliability. Alternative sets of explanatory variables could achieve greater country coverage, but not without compromising the quality of the regression estimates.

Separate regressions are run for financial assets, non-financial assets and liabilities. As errors in the three equations are likely to be correlated, the seemingly unrelated regressions (SUR) technique due to Zellner (1962) is applied, but only to financial assets and liabilities, since there are fewer observations for non-financial assets. The independent variables selected are broadly those used in Davies et al (2011). In particular, we include a dummy for cases where the data source is a survey rather than HBS data. This turns out to be negative and highly significant in the financial assets regression, indicating that the average level of financial assets tends to be much lower when the data derive from sample surveys. We use this result to adjust upwards the value of financial assets in the wealth level estimates for China, India, Indonesia, and Uruguay. We also include region-income dummies to capture any common fixed effects at the region-income level, and year dummies to control for shocks – like the recent financial crisis – or time trends that affect the world as a whole.

The resulting estimates of net worth per adult and the three components are reported in Table 2-4 for the years 2000 to 2016. HBS data are used where available (see Table 1-1); corrected survey data are used for China, India, Indonesia, and Uruguay in specific years. Financial assets and liabilities are estimated for 147 countries, and non-financial assets for 164 countries in at least one year using the regressions described in the previous section.

There remain 38 countries containing 3% of the global adult population without an estimate of wealth per adult. In order to generate wealth figures for regions and for the world as a whole, we assigned to each of these countries the mean wealth per adult of the corresponding region (six categories) and income class (four categories). This imputation is admittedly crude, but better than simply disregarding the excluded countries, which would implicitly assume (incorrectly) that the countries concerned are representative of their region or the world.

For a few countries, including the United States, wealth levels are available for the most recent years, including the first quarter of 2016. In order to obtain estimates of net worth per adult and its components we update the most recent available figures using, where available, house price growth for non-financial assets, market capitalization for financial assets and GDP per capita

growth for debts (see Table 1-4). Our projections are based on estimated relationships between these variables and the corresponding asset/debt totals in preceding years, rather than on proportionality. For countries without information on house prices and market capitalization, recent growth of GDP per capita is used to project net worth per adult forwards to mid-2016.

## 1.5 Wealth distribution within countries

An analysis of the global pattern of wealth holdings by individuals requires information on the distribution of wealth within countries. Direct observations on wealth distribution across households or individuals are available for 33 countries. One set of figures was selected for each of these nations, with a preference for the most recent year, and for the most reliable source of information. Summary details are reported in Table 1-5 using a common template, which gives the shares of the top 10%, 5%, 1%, together with other distributional information in the form of cumulated shares of wealth (i.e. Lorenz curve ordinates.)

The distributional data now available have certain fairly standard features. The unit of analysis is usually a household or family, but is in a few cases the (adult) individual. Household sample surveys are employed in almost all countries. The exceptions are the Nordic countries (Denmark, Finland, Norway and Sweden) and Switzerland which use data from tax and other registers covering the entire population. For all other countries, the wealth shares of the top groups are expected to be understated because wealthy households are less likely to respond, and because the financial assets that are of greater importance to the wealthy – for example, equities and bonds – are especially likely to be under-reported. Even in the U.S. Survey of Consumer Finance, where sophisticated measures are taken to counteract these problems, the sampling frame excludes the “Forbes 400” richest families, so that the extreme upper tail is not captured by design. And in those countries using register data there can be problems due to valuation problems, for example in connection with pension assets and life insurance.

The summary details reported in Table 1-5 show relatively sparse distributional information. Estimates for the empty cells were generated by an ungrouping computer program, which constructs a synthetic sample conforming exactly to any set of Lorenz values derived from a positive variable (Shorrocks and Wan, 2009).

For most countries lacking direct wealth distribution data, the pattern of wealth distribution was constructed from information on income distribution, based on the view that wealth inequality is likely to be highly correlated with income inequality across countries. Income distribution data for 166 countries was compiled from the World Development Indicators of the World Bank and the World Income Inequality Database, with priority given to the most recently available year. The ungrouping program was then used to generate all the Lorenz curve values required for the template employed for wealth distribution.

For the 33 countries which have data on both wealth and income distribution, the Lorenz curves for wealth are lower everywhere than for income, indicating that wealth is more unequally distributed than income. We grouped these 33 reference countries into two categories (European and North American countries with wealth per adult above USD 100,000 vs. the rest of the world) and computed for each category the average wealth to income ratio at various Lorenz points. Estimates of wealth distribution for the 135 countries lacking wealth data were then generated by scaling up the Lorenz figures for income by the relevant average wealth-income ratios.

For the purpose of generating regional and global wealth patterns, we assigned a wealth distribution pattern to each country lacking income distribution data equal to the (adult population weighted) average of the corresponding region and income class. This again was done in preference to simply disregarding the countries concerned.

## 1.6 Assembling the global distribution of wealth

To construct the global distribution of wealth, the level of wealth derived for each country was combined with details of its wealth pattern. Specifically, the ungrouping program was applied to each country to generate a set of synthetic sample values and sample weights consistent with the (estimated or imputed) wealth distribution. Each synthetic sample observation represents 10,000 adults in the bottom 90% of the distribution, 1,000 adults in the top decile, and 100 adults in the top percentile. The wealth sample values were then scaled up to match the mean wealth of the respective country, and merged into a single world dataset comprising 1.3 million observations. The complete global sample may be processed in a variety of ways, for example to obtain the minimum wealth and the wealth share of each percentile in the global distribution of wealth. The distribution within regions may also be calculated, along with the number of representatives of each country in any given global wealth percentile.

## 1.7 Adjusting the upper wealth tail

The survey data from which most of our wealth distribution estimates are derived tend to under-represent the wealthiest groups and to omit ultra-high net worth individuals. This deficiency does not affect our estimates of average wealth levels around the world, since these are determined by other methods. It does imply that the shares of the top percentile and top decile are likely to err on the low side unless adjustments are made to the upper tail. We would also not expect to generate accurate predictions of the number and value of holdings of high net worth individuals.

We tackle this problem by exploiting well-known statistical regularities in the top wealth tail and by making use of information on the wealth holdings of named individuals revealed in the rich list data reported by Forbes magazine and other publications. As described in more detail in Section 3, we use the number of billionaires reported by Forbes to fit a Pareto distribution to the upper tail of 56 countries. The revised top tail values in the synthetic sample were then replaced by the new estimates, and the resulting sample for each country was re-scaled to match the mean wealth value. This sequence was repeated until the process converged, typically after a few rounds. The overall global weighted sample still contains 1.3 million observations, each representing between 100 and 10,000 adults. The adjusted sample can be used to produce improved estimates of the true wealth pattern within countries, regions and the world. The minimum sample size of 100 allows reliable estimates of the number and value of wealth holdings up to USD 100 million at the regional and global level. Estimates above USD 100 million are obtained from projecting the Pareto distribution forward.

A further recent refinement allows us to pool the Forbes data for every year this century (currently 17 years). This produces more reliable wealth distribution estimates and enables us to produce a wealth sample for each year since 2000. The resulting data allow the trend in wealth inequality within countries and regions to be identified.

## 1.8 Concluding remarks

While the study of global household wealth is still in its infancy, enormous progress has been achieved in recent years. Data on the level of wealth are improving in quality and are available for more countries. Household wealth surveys have begun in a number of countries, including a major initiative within the Eurozone. In this work, efforts have been made to improve comparability by standardizing the definitions of the components of personal wealth and by seeking agreement on the appropriate methods of valuation. More needs to be done to improve the quality and frequency of wealth data, and to make the data available for a greater number of countries. In the meantime, we will continue to try to fill the gaps in the estimates of wealth level by country and to improve the estimates of wealth distribution within countries. In future, some revisions to our estimates are inevitable. Nevertheless, we are confident that the broad trends revealed in the Credit Suisse Global Wealth Report for 2016 will remain substantially intact.

## 2. Household wealth levels, 2000–2016

### 2.1 Introduction

As explained in the previous chapter, we aim to determine the level and distribution of household wealth across the world. The first stage in this process is to estimate the average level of household wealth and its core components for every country and every year since 2000.

Table 2-1 identifies 215 countries in 2016 and reports some core variables, including the classification by region, by income class according to the World Bank, and our assessment of the quality of wealth data.

Population figures are available for all countries and years and are reported in Table 2-2. Figures for the number of adults, i.e. individuals aged 20 or above, are also available for most countries and years. Where the data are not reported elsewhere, we estimate the number of adults by assuming that the adult ratio is the (population weighted) average for the corresponding region and income class. The results are summarized in Table 2-3.

The procedure outlined in Chapter 1 describes the three ways in which wealth levels data are assembled: direct estimates via national household balance sheets (HBS) or household surveys; regression estimates using likely correlated variables; and imputations based on the region-income class average. In practice, the situation is slightly more complicated because some countries have direct observations for, say, financial wealth, but require non-financial wealth to be estimated. The timeliness of direct data is greatly improved nowadays. For financial wealth at least, direct estimates for the first quarter of 2016 were available for 27 countries: Australia, Austria, Belgium, Canada, Chile, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Italy, Japan, Korea, Latvia, Lithuania, New Zealand, Poland, Portugal, Singapore, Slovakia, Spain, Sweden, the United Kingdom and the United States. These countries account for 76% of global wealth in 2016. In contrast, regression-based estimates are impossible for many countries in recent years because data is missing on core regressors. In these situations, wealth estimates are obtained by taking the figure for the most recent year and updating using subsequent movements in stock market indices, house price indices, or – if nothing better is available – growth of GDP.

In Table 2-1, we do our best to summarize the quality of wealth data for each country on a five-point scale. A country gets five points, and a good rating if it has complete HBS data, and either wealth distribution data or a good basis for estimating the shape of the wealth distribution. A satisfactory rating and four points go to countries that would get a good rating except that their HBS data does not cover non-financial assets. These countries must have a full set of independent variables allowing regression-based estimates of non-financial assets. Countries without any HBS data but with a household wealth survey or other wealth distribution data (from estate tax or wealth tax sources) get a fair rating and three points. A poor rating (two points) goes to countries without HBS or wealth distribution data, but having a full set of independent variables allowing estimation of their wealth levels. If some independent variables are missing but the regressions can still be performed, the rating is very poor (one point).

In Table 2-1, there are 42 countries for which wealth data quality is not assessed. These are the countries for which we have no sensible basis for estimating wealth. In calculating the regional and global wealth figures, we assign these countries the region-income class average; but the separate country data are not reported in the later tables.

## 2.2 Household wealth levels 2000–2016

Table 2-4 summarizes information on household wealth this century for 173 countries, five regions (excluding China and India), and the world as a whole. The data refer to end-year values during the period 2000–2016 and to mid-year values for 2015 and 2016.

Most of the column content is self-explanatory. The last column indicates the estimation method used for the wealth levels, grouped into five categories. Most figures up to 2008 are labeled as either (1) “HBS”, indicating data from official household balance sheets, (2) “survey data,” or (3) “regression,” referring to estimated values based on wealth regressions. When multiple methods are employed (e.g. for financial assets and non-financial assets), we report either “HBS” or “survey data” as appropriate. Two labels are typically reported for recent years. “Updated HBS” and “Updated regression” mean HBS data (respectively, regression estimates) updated using market capitalization growth for financial assets, house prices for non-financial assets and GDP per capita growth for debts. For countries lacking information on house prices or market capitalization, GDP per capita growth was used to project net worth per adult forward to the years 2010–2016.

Wealth estimates for recent years are subject to future revision as statistical agencies release more data. Wealth estimates for earlier periods should be less prone to change. As a rough guide, we expect that our wealth estimates prior to 2010 are not likely to change much in the future. However, statistical agencies occasionally make significant revisions to their historical data series – reflecting altered definitions of categories, or improved valuations, for example. When this happens, we are obliged to respect the new figures, and this can have repercussions for the wealth estimates of other countries, given the methods we employ. In addition, our methods are constantly being refined in response to new developments at the frontier of research. This too can affect the historical data, although mainly for countries with little hard evidence on wealth, and hence more reliant on the techniques used to derive our estimates.

## 2.3 Wealth trends 2000–2016

From the data reported for individual years, time series can be assembled for a number of important wealth variables. Table 2-5 provides examples for the world and for each region. They show that wealth per adult has grown from USD 31,651 to 52,819 over the period 2000–2016, an average growth rate of 3.4% per annum. Most of this growth occurred before the financial crisis. In the period since 2007 average wealth has stagnated in the world outside China and North America. However, the restrained performance in recent years is largely due to appreciation of the USD. When measured at constant exchange rates, wealth has grown at a consistent, albeit modest, rate during the whole post-crisis period.

Table 2-5 provides similar details regarding the relative importance over time of the three main subcomponents of household wealth: financial assets, non-financial assets (principally housing and land) and debts. At the turn of the century, financial assets accounted for 55% of gross household assets. This share fell until 2008, when it briefly touched 50%. Since that time non-financial assets have shown little growth worldwide, in contrast to financial wealth, which has grown robustly. As a consequence, the share of financial wealth recovered to 55% in 2015, roughly the same division of the portfolio as in 2000, although the share has dipped slightly during the past twelve months. Expressed as a proportion of household net worth, debt has moved in the opposite direction, and within a relatively narrow range. Globally, household debt rose from 14% of gross wealth in 2000 to 16% in 2008, and has since returned to the 14% level observed at the start of the century.

Finally, Table 2-7 extracts information on changes in household wealth in the 12 months to mid-2016. The United States continued its unbroken spell of gains since the financial crisis, but Japan took the lead this year with a rise of USD 3.9 trillion. The biggest loss was made by the United Kingdom, which shed USD 1.5 trillion in the wake of the vote to leave the European Union.

**Table 2-1: Country details**

Country	Region	Income Group	GDP per adult	Wealth per adult	Wealth per adult	Total wealth	Share of world wealth	Wealth data quality
			2016	2000	2016	2016	2016

## 3. Estimating the distribution of global wealth

### 3.1 Comparison with data from rich lists

Our method of estimating global personal wealth is essentially a bottom-up approach. It begins by establishing the average level of wealth in different countries onto which we graft the pattern of wealth holding derived from household surveys and other sources. Although sample surveys do not formally exclude high net worth (HNW) individuals with net assets above USD 1 million, they tend to be under-represented, and their wealth holdings are likely to be undervalued. The same is true to a greater extent of ultra-high net worth (UHNW) individuals with net assets above USD 50 million. In fact, the US Survey of Consumer Finances – which otherwise does an excellent job in the upper tail of wealth distribution – explicitly omits the 400 wealthiest families from its sampling frame. Evidence suggests that other countries fail to capture considerably greater numbers of individuals in high wealth categories. So further analysis and appropriate adjustments are required in order to construct plausible estimates of the number of wealthy individuals and the size of their holdings.

In order to proceed, we exploit the fact that the top tail of wealth distribution is usually well approximated by the Pareto distribution, which produces a straight line graph when the logarithm of the number of persons above wealth level  $w$  is plotted against the logarithm of  $w$ . Our data yield a close fit to the Pareto distribution in the wealth range from USD 250,000 to USD 5 million. Above USD 5 million the relationship begins to break down, and the correspondence weakens further above USD 50 million, as expected given the limitations of the data sources and the lumpiness caused when each sample observation represents at least 100 adults. However, it seems reasonable to use a fitted Pareto line to estimate the number of individuals in the highest echelons of the wealth distribution.

To determine the precise shape of the top wealth tail, we rely heavily on the rich list data provided by Forbes and other sources. We make particular use of the number of billionaires reported by Forbes, since the data are available for many years and are broadly comparable across countries. We recognise that rich list data have limitations. The valuations of individual wealth holdings are dominated by financial assets, especially equity holdings in public companies traded in international markets. For practical reasons, less attention is given to non-financial assets apart from major real estate holdings and trophy assets, such as expensive yachts. Even less is known – and hence recorded – about personal debts. Some people cooperate enthusiastically with those compiling the lists; others jealously guard their privacy. There are also different country listings for nationals and residents, which is especially evident for India, for instance. The true beneficial ownership within families adds further complications. Assigning the wealth recorded for Bill Gates, for example, to all family members might well result in several (unequal) billionaire holdings, so the number of billionaires would increase in this instance. In other cases, reassigning the family wealth would reduce all the individual holdings below the billionaire threshold. For all these reasons, rich list data should be treated with caution. At the same time, the broad patterns and trends are informative, and they provide the best available source of information at the apex of global wealth distribution.

### 3.2 Adjusting the wealth pattern in the top tail

To mitigate some of the problems associated with small numbers of billionaires, we disregard countries that have a single billionaire or that appear in the Forbes list for fewer than five years. About 50 countries survive the cut. A further level of refinement involves converting the number of Forbes billionaires – which we assume refers to billionaire families – into the equivalent number of high wealth adults. Our first attempts to absorb the Forbes data used the data for a single year and identified the Pareto distribution which could be grafted onto the upper tail in order that the new distribution is consistent with the reported number of billionaires. Replacing

the initial sample observations in the top tail with the fitted Pareto values typically changes the sample mean. So the sample values were then scaled (usually down) in order to restore consistency with the correct sample mean, and the steps repeated until the process converged, typically in a few rounds.

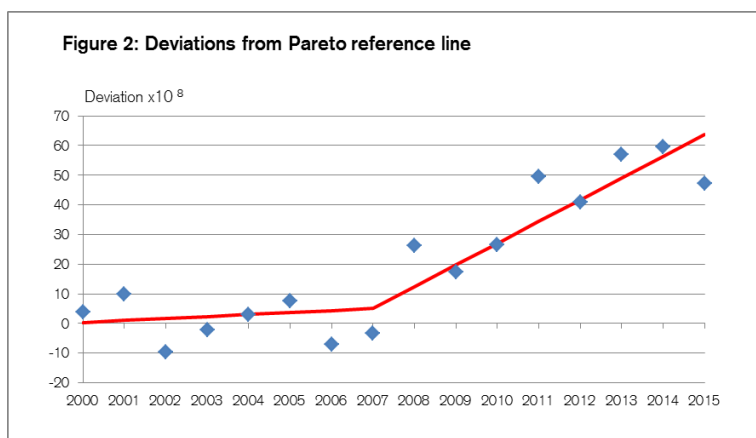

This is an adequate method of constructing the wealth distribution for a single year, although the estimates may be sensitive to relatively small year-on-year variations in the Forbes data. These year-on-year variations may also make it difficult to identify with confidence trends in inequality over time. Recently we have managed to mitigate both of these problems by pooling the Forbes data for the entire period since 2000. This is achieved by modifying the way that the Pareto tail is plotted, so that the vertical axis now indicates the logarithm of the *fraction* of adults above a given wealth level  $w$  and the horizontal axis represents wealth  $w$  expressed as a *multiple of mean wealth*, again on a logarithmic scale. The curve generated by the wealth sample is now unchanged if the sample is replicated or if all wealth values are scaled up or down by the same factor. Its form depends only on the degree of inequality, as captured by the Lorenz curve. And the modification allows all the Forbes points to be plotted on the same graph – as illustrated in Figure 1 for data the United Kingdom – regardless of how fast the adult population or mean wealth have changed over time.

Source: Original estimates; see text for explanation of methods.

If the aim is to generate a single wealth distribution, then an average value can be constructed from the Forbes data, and the procedure described earlier used to graft on a Pareto tail, as illustrated in Figure 1, with the expectation that averaging the Forbes data points will improve the reliability of the results. We aim to go further and generate plausible estimates of the change in wealth distribution over time. To do so, we attempt to smooth out the data over time by calculating the deviations of the Forbes points from a reference distribution (for example, the dotted line in Figure 1) and then seek an explanation for the pattern of deviations.

Figure 2 illustrates the outcome for the UK data from Figure 1. A number of factors might help explain the deviation, including, for example, the share of financial assets in total wealth and the year-on-year change in the exchange rate. At present, however, we have focussed our attention on the trend over time, with a possible structural break in 2007, which the pattern for many countries suggests may be appropriate. The fitted line Figure 2 confirms the structural break in 2007 for the UK data and suggests that inequality changed little in the UK before the financial crisis, but has since been trending upwards, although quite modestly given the bunching of data points in Figure 1.

Source: Original estimates; see text for explanation of methods.

The final step in our procedure replaces the observed Forbes data points with the smoothed value obtained from the fitted deviation line and then fits a Pareto top tail to the wealth distribution in each year in the way described above. The adjusted wealth samples for the United Kingdom confirm the relatively small changes in inequality over time that one would expect from the pattern shown in Figure 2. For other countries – China and India, for example – the pattern of deviations show a stronger trend over time and the adjusted samples indicate a significant shift towards more inequality. Adjusted samples are obtained in this way for each country that has a sufficient number of billionaires. For other countries, we apply the same method to each of the regions while keeping note of which observation relates to which country, and then extract the adjusted wealth sample for each member country.

### 3.3 Features of the global wealth distribution

Application of the top tail adjustment results in a synthetic sample containing 1.3 million observations for each year since 2000. Each observation represents approximately 10,000 adults at lower wealth levels and 100 adults at the top end. These samples can then be processed to generate summary data on the wealth pattern within countries, regions and the world.

Table 3-1 reports figures for individual countries, and Table 3-2 provides more detail at the regional level. The results allow us to visualize the global wealth distribution in the form of a wealth pyramid which places adults in one of four wealth bands: under USD 10,000; between USD 10,000 and USD 100,000; between USD 100,000 and USD 1 million; and over USD 1 million. The base level of the pyramid contains 3.5 billion adults, or 72% of the global population, but accounts for only 2.4% of global wealth. In contrast, dollar millionaires comprise 0.7% of all adults, but collectively own 46% of all assets. For adults with wealth exceeding USD 100,000 and USD 1 million, Table 3-3 provides further summary information for individual countries.

Combining the samples for all countries allows the features of the global distribution of wealth to be identified, including, for instance, the minimum wealth of each percentile (i.e. 1% group) worldwide and the share of total wealth owned by this group. To be among the wealthiest half of the world in mid-2016, Table 3-4 shows that an adult needs only USD 2,220 in assets, once debts have been subtracted. However, a person needs at least USD 71,560 to belong to the top 10% of global wealth holders and USD 744,400 to be a member of the top 1%. Taken together, the bottom half of the global population own less than 1% of total wealth. In sharp contrast, the richest decile hold 89% of the world's wealth, and the top percentile alone account for 50% of global assets.

The decile breakdown by regions has a number of interesting features. China dominates the upper middle section of the global wealth distribution, accounting for 40% of members of deciles 6–9. In contrast, residents of India are heavily concentrated in the lower wealth strata, accounting for over a quarter of people in the bottom half of the distribution.

Table 3-4 shows that residents of Latin America are spread quite evenly across the global wealth spectrum. The Asia-Pacific region (excluding China and India) mimics the global pattern more closely still, although the apparent uniformity of the Asia-Pacific region masks a substantial degree of polarization between high-income countries, such as Hong Kong, Japan and Singapore, and lower income countries, such as Bangladesh, Indonesia, Pakistan and Vietnam. In fact, when high-income countries are excluded from the Asia-Pacific group, the wealth pattern within the remaining countries resembles that of India. Residents of Africa are also heavily concentrated at the bottom end of the wealth spectrum: half of all African adults are found in the bottom two global wealth deciles. In sharp contrast, North America and Europe are heavily skewed toward the top tail, together accounting for 64% of adults in the top 10%, and 77% of those in the top percentile.

Table 3-5 lists the countries that have gained or lost the most number of members of the global top decile and percentile during the year to mid-2016. It also reports changes in the number of millionaires during the past twelve months.

### 3.4 The number of high and ultra-high net worth individuals

Apart from the rich lists, which cover a relatively small number of named individuals, there is a scarcity of information on wealth holdings above USD 1 million. Survey details are patchy at best, and official statistics based on tax returns are often inadequate given the complexity of wealth ownership arrangements. Our method of adjusting the top tail using rich list data pooled over several years helps to bridge this gap. Smoothing the wealth distribution at the top end by means of a Pareto curve fitted to the data for each country then produces plausible estimates of the global pattern of asset holdings in the high net worth (HNW) category from USD 1 million to USD 50 million, and in the ultra-high net worth (UHNW) range from USD 50 million upwards.

Table 3-6 reports the numbers for mid-2016. While the base of the wealth pyramid is occupied by people from all countries at various stages of their lifecycles, HNW and UHNW individuals are heavily concentrated in particular regions and countries, and tend to share more similar lifestyles, participating in the same global markets for luxury goods, even when they reside in different continents. The wealth portfolios of these individuals are also likely to be more similar, with more of a focus on financial assets and, in particular, equity holdings in public companies traded in international markets.

For mid-2016, we estimate that 32.8 million HNW adults have wealth between USD 1 million and USD 50 million, of whom the vast majority (28.9 million) fall within the USD 1–5 million range. North America accounts for the greatest number, significantly above Europe, which in turn hosts nearly double the number in Asia-Pacific countries, excluding China and India. China, Latin America, India and Africa together account for less than 8% of all HNW individuals.

UHNW individuals with net assets above USD 50 million now number 140,900 worldwide by our calculations. Among individual countries, the United States leads with 50% of UHNW adults. China has recently moved into second place, but is a distant second with only 8% of the total membership.

**Table 3-1: Wealth pattern within countries, 2016**

Country	Adults	Mean wealth per adult	Median wealth per adult	Distribution of adults (%) by wealth range (USD)				Total	Gini %

## 4. The bottom billion

### 4.1 Introduction

The assets and debts of the 2.4 billion adults in the bottom half of the global wealth distribution are often neglected. In the wake of the microfinance movement, and with more research being done on the “wealth poor”, that neglect is being redressed (Collins et al., 2009; Azpitarte, 2011; Townsend, 2013; Wolff, forthcoming). This chapter summarizes what we know about this group, with a special focus on the roughly one billion adults who fall within the bottom quintile (i.e. the lowest 20%).<sup>1</sup>

One reason for past neglect of the bottom billion is that membership was heavily concentrated in poorer parts of the developing world. The problem of low assets could therefore be dismissed as just another facet of low resources and low living standards associated with poverty. This is still largely true, and likely to continue: people with low income and high needs will always struggle to acquire and retain assets. However, as successful microfinance and poverty alleviation initiatives have illustrated, that struggle can be made easier with good institutions (de Aghion and Morduch, 2005). And at the other end of the spectrum, higher income does not guarantee more wealth. The past 20 years have seen an increasing incidence of low wealth in high income countries. Successive wealth surveys document this trend in individual countries. Another important development is the increasing likelihood that low wealth holdings involve negative net worth, with debts exceeding the value of assets. This trend applies not only to developed countries, but throughout the world, as the latest wealth survey data for China and India attest. It assumes particular significance in the context of concern about growing wealth inequality, because – in simplistic terms – growing inequality can arise because the wealthiest individuals pull away at the top, or the least wealthy individuals fall further behind at the bottom. Public discussion tends to focus on the top tail, but attention in the future may well shift towards adverse movements in the net worth of the wealth poor.

Another reason for neglect concerns data problems. Personal debt is especially important amongst the wealth poor, and is sometimes difficult to estimate given reluctance among survey respondents to admit to indebtedness. This problem appears to be most acute in lower income countries. Secondly, wealth surveys in high income countries generally omit consumer durables, such as furniture, clothes and household appliances.<sup>2</sup> These assets are often purchased on credit, which leads to an exaggeration of wealth poverty in surveys since the debt incurred is captured but the offsetting asset is not. There are limits as to what extent these problems can be overcome, but we strive to draw on all the available sources, including numerous micro-data sets, in order to address a number of important questions, such as: where are low wealth holders located around the globe?; what household characteristics are most associated with the bottom wealth groups?; what types of assets do they own?

### 4.2 The global lower tail

The world has a great number of people with relatively little wealth. According to our estimates, half of all adults in the world own less than USD 2,222, and the bottom 20% of adults own no more than USD 248. The average wealth of people in these slices of the distribution is correspondingly low: just USD 984 for the bottom 50% and minus USD 1 for the bottom 20%. The mean wealth of the bottom quintile reflects the fact that 44% of this bottom group are debtors, with average net debt of USD 2,628.

---

<sup>1</sup> The “bottom billion” phrase was introduced by Collier (2007), for whom it referred mainly to the people living in 58 countries he believed were in a development trap that prevented them from rising out of poverty.

<sup>2</sup> In contrast, the wealth surveys in China, India and Indonesia all cover household durables. See Subramanian and Jayaraj (2008), Li and Wan (2015) and the entry for Indonesia in the Data References section.

Table 4.1 shows the percentage of adults in each region with negative wealth, and the percentage in the global bottom half and the global bottom quintile. The most striking feature is the similarity across regions in the proportion with negative wealth. This was not evident in the past: surveys for China and India used to display low incidences of negative wealth. It was widely believed that debt was underreported, so Table 4.1 may reflect improved data collection. However, the problems of data quality caution against placing too much confidence in the pattern of negative wealth holdings that we reveal.

In the context of the broader global lower tail categories, incidence differs greatly between regions. India and Africa both have a disproportionate share: 80% of adults in India are in the global bottom half, and Africa is close behind at 79% (Table 4.1). The incidence in Asia-Pacific (49%) effectively matches the global average, whilst Latin America (39%) is lower than average. It is interesting to note that the proportion of low wealth holders in China – with 35% of adults in the global bottom half – is very similar to the European figure of 34%. Levels in North America are significantly lower than anywhere else: only 9% of adults have wealth below the global median value.

While the gap between Europe and North America may seem surprising, Europe is a less homogeneous region than North America. As well as high-wealth countries in the North, it includes countries with much lower wealth in the East and South. The contrast between China and India may also come as a surprise, given their similarities in terms of huge populations and rapid growth. Their representation in the global bottom half is very different, and the discrepancy is even greater in the bottom quintile, which covers 31% of Indians but only 7% of Chinese.

Another interesting observation is that even in North America, there are many people in the global bottom quintile. This highlights the fact that there are significant numbers of low-wealth citizens in high-income countries, including many whose debts exceed their assets. In North America, almost all of those in the global bottom quintile have negative wealth. To some extent, this reflects poverty and the relative ease of borrowing, but it also reflects the fact that the valuations of offsetting assets and debts can be treated differently in wealth surveys. Taking out a mortgage to buy a house makes little difference to net worth, since in this case both the asset and debt are recorded in a wealth survey. However, the value of durables other than vehicles is typically not included in wealth surveys in high income countries. If such assets are financed by consumer borrowing, the debt is recorded in a wealth survey but the offsetting asset is not, reducing estimated net worth. Similarly, student loans help create human capital, but do not produce a balancing asset in the household wealth calculations.

### 4.3 Where do the bottom billion live?

With both large populations and a high incidence of low wealth, Africa and India – as expected – account for a high proportion of the bottom tail. As Table 4.2 shows, 486 million members of the bottom quintile – almost exactly half of the bottom billion – live in Africa or India, and 1.1 billion adults there fall within the bottom half of the global wealth distribution. The other major concentration is in the Asia-Pacific region, particularly the low-income countries of South Asia and South East Asia. Together, Africa, India, and Asia-Pacific account for 72% of the bottom billion by wealth, and 70% of the bottom half. The remaining 30% are mainly spread across China, Europe, and Latin America.

Table 4.2 also reports the number of adults in the bottom billion for all countries that have more than 20 million members. India leads again, but due to its huge population, China now figures significantly, with 72 million members, despite its relatively low incidence rate. Population size is evidently the principal reason why other countries are listed: populous African countries – Nigeria, Ethiopia, and the Congo DR – contribute 35, 27, and 25 million members respectively, while in the Asia-Pacific region, Bangladesh, Indonesia, and Pakistan supply 33, 30, and 22 million respectively. Latin America has only one representative – Brazil with 24 million members – with the sizeable low-wealth population in the region being split between many smaller countries. Finally, the USA is also listed, with 21 million members, due to its large population and fairly high incidence of low wealth. The appearance of the USA in the asset poverty list alongside Pakistan, Congo, and Ukraine may surprise some, although the reasons given earlier make it understandable.

#### 4.4 Incidence of low wealth across countries

While differences across countries in the absolute number of adults in the wealth lower tail are important, so too are variations in the incidence rate. Table 4.3 shows the percentage of adults in selected countries in the global lowest 20% or 50% in 2016. There is a very wide spread. Countries from Africa and low-income parts of the Asia-Pacific region dominate the highest incidence ranges, in terms of both the bottom 20% and the bottom 50%. Here, it is typical for at least 40% of a country's population to be in the bottom 50%, and for at least 20% to belong to the bottom quintile. Latin America, Eastern Europe, and Southern Europe appear in the middle range, with 20% – 40% of adults in the bottom half of the global wealth distribution. Then come Northern Europe, North America, and high-income Asia-Pacific countries, with lower incidence. Interestingly, the frequency of net-indebted adults is fairly constant across countries and regions. What is noticeable about Northern Europe and North America is the scarcity of wealth holdings that are positive but small enough to fall within the bottom half of the global wealth distribution. There are some deviations from this pattern, of course. Russia has high incidence, for example, compared to other East European countries such as Poland and the Czech Republic, while Chile and Uruguay – the highest income countries in Latin America – have markedly lower incidence than other countries in their region.

#### 4.5 Change in incidence over time

While the proportion of global adults in the bottom wealth quintile of course does not change over time, the pattern of membership can vary across regions and countries. Table 4.4 shows the change in the membership share for 2000–2016, subdivided into the years up to the financial crisis, and the period since then. For most countries, the changes in membership barely register, but for regions the changes are quite noticeable. Africa increased its share of the bottom quintile from 18.6% in 2000 to 24.7% in 2016, with two-thirds of the increase occurring since 2008. The share also rose significantly in India, but by a little less than in Africa – 4.6% overall compared to 6.1% – and its rate of increase has been slowing since the financial crisis. The explanation for these large changes is clear: both regions experienced rapid population increases, and the growth of household wealth was unable to keep pace, at least when measured in USD using current exchange rates.

Wealth growth has been faster in China and, more importantly, population growth has been slower. As a consequence, Chinese representation in the bottom quintile of wealth holders has halved, dropping from 14.1% in 2000 to 12.2% in 2008, and then more precipitously to 7.5% in 2016. The rest of the Asia-Pacific region also had a favorable wealth/population growth environment, which reduced its proportion of the lowest wealth quintile from 24.5% to 22.2%, primarily since 2008. Wealth and population growth were evenly balanced in Latin America, so its share of the bottom quintile has barely changed. North America also saw little change for different reasons: wealth grew considerably faster than the adult population, but the wealth growth bypassed those in the bottom global quintile, who are predominantly net debtors. Europe was the anomaly: membership of the bottom quintile fell significantly, from 12.3% in 2000 to 8.7% in 2008, but then rose back to 10.4% in 2016. This is largely attributable to the wealth repercussions of an appreciating euro (and other currencies rising) during 2000–2008, and to the reversal of the trend over 2008–2016.

Similar considerations apply to individual countries, but the global impact is often imperceptible due to relatively small populations. Population growth caused the share of members from Nigeria to almost double, from 2.0% in 2000 to 3.6% in 2016. Congo and Egypt also experienced a modest rise (both up 0.4%), although decreasing average wealth is part of the explanation for Egypt. Indonesia and Philippines both succeeded in reducing their share of the bottom wealth quintile, by 1.1% and 0.4% respectively. Russia also improved during the early years, almost halving its share from 3.7% in 2000 to 2.0% in 2008, but that climbed back to 2.9% in 2016, largely because of the weakness of the ruble. Ukraine followed a similar – but even more volatile – pattern; its share dropped from 2.1% in 2000 to 1.3% in 2008, and then rose to 2.5% in 2016 as a result of currency depreciation, conflict and deteriorating conditions.

## 4.6 Determinants of low wealth within countries

To understand who belongs to the lower global wealth tails – apart from simply their country or region of residence – it is necessary to obtain information about the characteristics of low wealth holders within individual countries. Fortunately, there is a growing list of countries that have household surveys of assets and debts which can be used for this purpose. The European Central Bank (ECB) has coordinated Household Finance and Consumption Surveys (HFCS) in most Eurozone countries. These give good coverage in Northern and Southern Europe (seven and five countries respectively). To this, we have been able to add seven other countries from Eastern Europe, the western hemisphere, and South Asia. This allows for a broad international comparison of wealth-holding at micro level. To achieve comparability, we focus on the characteristics of the bottom quintile of wealth holders within each country.

Unsurprisingly, low wealth tends to be associated with low income or high debt. In most countries, it is also associated with owning few real assets: on average 58% of households that have less than a quarter of their assets in non-financial form are in the bottom wealth quintile. Most households with few real assets are not home-owners, so this finding supports the contention that home-ownership is a key element in building household wealth.

To gain further insight we estimated a probit model for each country using household data. The dependent variable is the probability of that a household will be in the bottom 20% of the wealth distribution in its own country. The explanatory variables are mostly characteristics of the head: age, education, sex, work status, education. We also control for the number of children and whether the household is based on a single person or a married couple. Results are shown in tables 4.5 and 4.6.

Table 4.5 summarizes the marginal impacts or "risk factors" for low wealth associated with the various household characteristics. The cell entries refer to the extra likelihood of being in the bottom quintile compared to a benchmark household consisting of a married couple with no children, and a male head aged 45-54 who is employed and has a tertiary education.

The results show that the factors most associated with being in the bottom wealth quintile are being young, single, or poorly educated. Secondary factors are having three or more children, or being in the "other not working" category (i.e. unemployed or out of the labor force, rather than retired). In most places, the biggest risk is being aged below 35, which raises the probability by 15% on average. This is not unexpected, and reflects the fact that those younger than 35 are at the beginning of their life-cycle of saving and wealth accumulation. In recent years, however, the young have faced particular difficulties, including a disproportionate rise in unemployment in the wake of the global financial crisis. The greater frequency and size of student loans are also likely to have increased the probability that the young will be in the bottom tail of the wealth distribution. The impact of these factors appears to have been particularly strong in the United Kingdom, where the additional risk of being in the bottom wealth quintile if aged less than 35 is estimated to be over twice as great as the average across countries.<sup>3</sup>

The likelihood of having low wealth declines as we move from the young to the middle-aged, and on to households with a head aged 55-64. While this is to be expected, we also see that the decline continues when the head is aged 65-74, or even above 75 years in Northern Europe, the United Kingdom or the United States. This may reflect a desire to maintain wealth to pass on to the next generation via bequest, or reluctance to dissave in the face of uncertainty about future income or the length of the remaining lifetime. It also reflects the fact that poor people tend to die earlier, so cohorts of survivors become wealthier on average as they age for compositional reasons.

Table 4.6 casts more light on the risk of being wealth poor by reporting the likelihood of being in the bottom wealth quintile for a range of typical household types. Being young, single and female puts a person at relatively high risk everywhere, while being a young single mother with low education is generally worse than being a young single female with a good education and a job.

In Indonesia, among the household types considered a married couple aged 45-54 with a head who has a high level of education and a job is least likely to be wealth poor. In line with the

---

<sup>3</sup> See also Azpitarte (2011) regarding age effects on wealth poverty in the UK.

results in Table 4.5, however, there are couples in other countries aged 65-74 who do better than those aged 45-54, even if the head only has secondary education. In this age group, there is also little difference between couples whose head is still working, and those with retired heads.

#### 4.7 Composition of the lower wealth tail

Risk factors are informative, but they do not reveal the composition of the lower wealth tail. A group with high risk but very small numbers will not feature strongly among the wealth poor. For example, people with only primary education are usually at high risk of having low wealth, but they do not form a large contingent of the wealth poor in countries where very few people have only primary schooling. Table 4.7 reports the breakdown in the bottom wealth quintile according to the age, sex, marital status, work status and education of the head, as well as the number of children. In all cases, households with heads aged less than 35 are the largest age group among the wealth poor. There is variation in other respects, however. The elderly form a small component in India and Indonesia, for example, but they make up a much larger proportion in Southern Europe, where the young are less prominent. These variations largely reflect differences in the age structure of populations across countries.

The impact of gender, education, and work status of the head on membership of the bottom wealth quintile differs significantly across countries. In Chile and Uruguay, for example, almost 70% of household heads in the bottom wealth quintile are female. In contrast, in India and Indonesia the proportion is only about 20%. Whatever the cause, this suggests that policies to boost the wealth of female-headed families are likely to have more impact on the lower wealth tail in Chile and Uruguay than in India and Indonesia. Similarly, large differences according to education are seen, even between countries that are less widely separated geographically and economically. In Southern Europe, for example, a relatively high proportion of the low wealth group does not have a secondary education, whereas the corresponding proportion is much smaller in Northern Europe or North America.

Differences related to work status are also seen across countries. Households with employed heads form the largest group everywhere apart from the UK, so it is a mistake to imagine that the typical low wealth household has an unemployed head. Retirees constitute the second largest group in Southern Europe and the United States. Except for the UK, two-thirds or more of households in the bottom wealth quintile have a head who either is currently working, or is retired from work.

#### 4.8 Assets and debts of the lower tail

The type of assets held by low wealth holders, and their degree of indebtedness, are important to understanding the situation of the bottom billion. For low income countries the best evidence available comes from the wealth surveys in China, India and Indonesia. For low income countries the best overall evidence comes from studies in China, India, Indonesia and Thailand (Frankenberg et al., 2003; Subramanian and Jayaraj, 2008; Samphantharak and Townsend, 2013; Townsend, 2013; Li and Wan, 2015). These show that real assets, including household durables and transport equipment as well as farm assets in rural areas, dominate the portfolios of the poor. On average, in wealth surveys both financial assets and debt are relatively small compared with real assets for the wealth poor. However, some are of course severely indebted, and there is much informal borrowing and lending activity among the wealth poor, as found in the diary studies of Collins et al. (2009).

Turning to the developed world, Table 4.8 summarizes what can be gleaned from the HFCS surveys for the Eurozone conducted mainly in 2010, and from the US Survey of Consumer Finances for 2013. For both sets of data, the bottom groups are heavily indebted: debt-to-asset ratios are around 100%. Financial assets are skewed toward deposits, and stocks, bonds and mutual funds are less important. The difference is much less marked in the United States, however, where these assets are more widely held than in Europe (Haveman and Wolff, 2004).

Regarding non-financial assets, in both Europe and the United States the principal residence is more important for the bottom group than for the whole population. In other respects, however,

there are marked differences between Europe and the United States. For example, the bottom quintile in Europe held 15.6% of non-financial assets in "other real estate"; such holdings were too small to be estimated reliably in the United States. This difference may reflect, in part, the fact that urban dwellers in Europe often retain small landholdings in rural areas, whereas that is unusual in the United States. The large "other" non-financial holdings of the bottom quartile in the United States comprise mainly vehicles.<sup>4</sup>

The debt situation of the bottom groups is of special interest. Mortgages make up around 80% of all household debt in both Europe and the United States. They are less important for the bottom groups, but in Europe, mortgages account for 64.4% of total debt for the bottom quintile, compared to just 42.5% of total debt for the bottom quartile in the United States. This reflects greater reliance on lines of credit, credit cards, and installment loans in the United States. Credit card debt is shown separately in Table 4.8, and is a significant part of debt for the bottom group in the United States, at 3.4% of total debt for all households together and 11.4% for the bottom quartile. This is not the case in Europe, where it is just 0.2% of debt for all households and 0.3% for the bottom quintile. Student loans (referred to as education loans in the survey) are reported separately in the United States, where they form 27.8% of the debt of the bottom quintile. This reflects a significant and widespread change in the composition of household debt in the United States (Wolff, forthcoming). Before 2010, student loans made up about 30% of installment debt for households in general, and around 45% for those in the bottom quartile. Those numbers rose to 45% and 65% respectively in the 2010 survey, and had risen again to 49% and 66% by 2013.

## 4.9 Conclusion

In population terms, the lower tail of the global wealth distribution is most concentrated in India and Africa, with sizeable representation also in the less prosperous countries of the Asia-Pacific region. These three areas host 70% of the world's least wealthy half, and 73% of the bottom wealth quintile. Our calculations suggest that 80% of adults in Africa and India belong to the bottom half of the global wealth distribution. The incidence of wealth poverty is moderate in China and Latin America, with just 35% and 40% of adults respectively in the bottom 50%. With its very large population, China has 15% of the global number in this category, but since the turn of the century, its share of the global bottom quintile has fallen significantly, and is now only 7%. The places vacated by China in the global bottom quintile have been occupied by countries and regions with rapid growth of population relative to wealth, predominantly India and Africa. There are significant numbers of people who are wealth poor by global standards in North America and Europe, with 9% of North Americans, most with negative net worth, in the global bottom quintile and 34% of Europeans in the global bottom half.

Within countries, the major "risk factors" for households being wealth poor are having a head who is young, single or poorly educated. The likelihood of a household being in the bottom wealth quintile tends to fall steadily with the age and education of the head, and is also lower where household heads are in employment or retirement, and if they are married. While households whose head is either unemployed or out of the labor force are over-represented among the wealth poor, the majority of those in the bottom wealth quintile are either employed or retired. Being well educated reduces the chances of being wealth poor, but it does not offer complete protection. In particular, it is not uncommon to find well-educated young people in the bottom wealth quintile. Although this is largely a consequence of the young being at the start of their life-cycle of wealth accumulation, it also reflects poorer job prospects in recent years and mounting student debt in some countries.

## 5. Composition of wealth portfolios

### 5.1 Financial versus non-financial assets

We look first at the relative importance of financial versus non-financial assets in the average household portfolio. Expressed as a percentage of gross household assets, the pattern clearly differs markedly between poorer and richer countries and regions, as can be seen in Table 5-1, which shows the breakdown for the countries where we have the best data. In developing countries, for example India and Indonesia, it is not unusual for 80% or more of total assets to be held in the form of non-financial assets, including housing, farms and small business assets. This pattern is also associated with the relative under-development of financial institutions in many lower income countries.

As countries develop – and make the transition to a market economy – the importance of non-financial assets tends to decline. An interesting example is provided by China, where the share of financial assets is 47% in 2016. Another example is provided by Singapore, a country further along the development path, but still nevertheless seeing the share of financial assets in household portfolios continuing to rise – from 44% in 2000 to 54% in 2016. In the richest countries, financial assets typically account for more than half of household wealth. An important example is the United States, where about 70% of household assets have been held in financial form in most years since 2000 (although the share is somewhat inflated by the US practice of classifying all business equity as a financial asset).

There are interesting exceptions to this general pattern. Robust house price rises drove the share of non-financial assets above 60% in France and Italy by 2008 and it has since remained relatively high in those countries. The share of non-financial assets also rose in the United Kingdom, from 44% in 2000 to 55% in 2007, although it has since fallen back to 48%. In the developing world, South Africa is a strong outlier, having an exceptionally high share of financial assets: the share of 65% in 2016 exceeds that found in all G7 countries except the United States. This high share reflects, on the one hand, the advanced development of South Africa's financial institutions including its private pensions, and on the other hand, relatively low house prices.

### 5.2 Composition of Financial assets

Table 5-2 provides some detail on the composition of financial assets, for a greater number of countries. It shows the breakdown into three categories: currency and deposits (liquid assets); equities (all shares and other equities held directly by households); and other financial assets. In most countries the reserves of life insurance companies and pension funds form the largest component of "other financial assets" – these reserves comprise equities and other financial assets that are in effect being held on behalf of the household sector.

The composition of financial assets differs considerably across countries. One interesting aspect is that equities held directly are not always a large component of household financial wealth, even in countries with very active financial markets. In the United Kingdom and Japan, for example, equities account for 10-15% of total financial assets. In contrast, they make up 35% of financial assets in both Sweden and Italy, 39% in Belgium and 44% in the United States. To calculate the overall percentage of the household portfolio held in equities, equities held indirectly via insurance policies and pension plans would need to be added to the total of equities held directly. However, this is not possible since the household balance sheet data available in most countries do not show the composition of assets held in insurance and pension reserves. If the purpose were to find out the total exposure of the household sector to stock market risk, it is also not clear that this exercise would provide the answer. Households have

explicit or implicit guarantees on their rights to most insurance and pension benefits, so that the risk characteristics of the latter generally differ from those of the assets held in the reserves.

Where equities account for more of the portfolio, there is less room for liquid assets or other financial assets. The strongest negative association is between equities and other financial assets, perhaps because other financial assets are larger where private pension systems are more highly developed and may tend to crowd out privately held equities. A good example of this phenomenon is found in Australia, where only 18% of the average portfolio is in equities vs. an average of 29% for the countries in Table 5-2 showing 2015 data, but other financial assets have a share of 60%, well above the average figure of 38%. A similar pairing of below-average equities and above-average other financial assets is seen, in most years, in nine countries in Table 5-2, including Chile, France, Germany, Norway, and the United Kingdom. The opposite case, of above average equities and below average other financial assets is found in eight countries, which include some transition economies as well as Austria, Belgium, Finland, Italy and Spain. The negative association between equities and liquid assets is weaker, but shows up in countries like Japan where liquid assets are 51% of the portfolio versus 16% for equities, and at the opposite end of the scale the United States, with only 15% in liquid form versus 44% in equities.

There are also interesting differences across country types. The typical portfolio in the well-established high-income market economies has less liquid assets than average, equities at about the average level, and other financial assets somewhat above average. Emerging market countries have less in both equities and other financial assets than the established high income countries, and therefore a higher share in liquid assets than seen in the typical rich country. The transition countries have more in liquid assets than either the high income countries or emerging market economies, perhaps reflecting the fact that their financial systems have had less time to develop.

### 5.3 The impact of the global financial crisis

While the financial crisis of 2007-2008 is receding into the past, it was a landmark event for household wealth, bringing an abrupt decline in most personal fortunes and a change in household behavior and wealth performance in most countries. In light of these aspects, it is interesting to examine how the overall composition of personal wealth and, in particular, the proportion of financial assets to total household assets has changed over the past decade. A decline in the relative importance of financial assets was seen in a number of countries in 2008, for example in Denmark, Italy, Switzerland and notably China. In other countries, the credit crisis depressed both property prices and share values, so the share of financial assets was more stable; little change was seen in 2008 in the share of financial assets in the United Kingdom and the United States. Only in the Czech Republic and New Zealand did the relative size of financial assets increase appreciably in 2008.

Longer term, the share of financial assets does not often appear to change dramatically. In France, a relative increase in property prices in the period since 2000 has reduced the share from 45% to 39%, and a similar effect is seen in Italy, where the share fell from 47% also to 39%. Elsewhere, however, effects generally seem to be mostly short term. The United States showed a relative decline in financial assets from 2000 to 2005, for example, but then with a booming stock market the share rebounded. Its rise was only halted temporarily by the financial crisis. Now the share is 72%, significantly above its 2000 level of 69%. Japan shows a rise in the proportion of financial assets during 2000–2006, a decline during the financial crisis, and a small subsequent increase; the share is now back to about the level of 2005. Among major developing nations, the financial asset share has risen gradually in both India and Indonesia.

The importance of debt has also changed over the last fifteen years. For many countries, including the United Kingdom and the United States, there was a significant rise in the period leading up to the financial crisis and a decline thereafter. However, this experience is not universal. In Japan, for example, the debt ratio was steady from 2000 to 2008, and in Germany it fell over that period. What is common to most OECD countries, however, is that the debt ratio fell after the financial crisis. So where debt had not risen before the crisis, it nonetheless tended to fall afterwards – from 16% to 14% in Japan, for example, and from 15% to 13% in

Germany. Contrasting post-crisis results are seen in a few high income countries where the debt ratio held steady, as in France, or even rose a little, as in Australia. Trends also differed in rapidly developing countries like China, India and Indonesia, which saw their debt ratios rise throughout the decade, seemingly unaffected by the global financial crisis.

## 5.4 Conclusion

The composition of household balance sheets is an important determinant of trends in consumption and investment, and in many ways reflects the financial development of individual countries. For instance, debt as a proportion of total household assets tends to be low in developing and some transition countries because financial intermediation and property rights are underdeveloped, while debt levels in OECD countries are relatively high, reflecting a more developed financial system.

Our analysis of household balance sheets examines financial and non-financial assets and debt from a global perspective. In general, non-financial assets like housing, land and small business assets make up a relatively large proportion of household wealth in the developing world and in transition countries. While their relative importance is smaller in the high income countries there is variation. Non-financial assets are still quantitatively more important than financial assets in Australia, France, Germany, Italy and New Zealand. In contrast, financial assets form a large proportion of the household balance sheets in countries like the United States, Japan and the Netherlands.

## 6. Region and country focus

### 6.1 Introduction

Countries differ greatly in terms of their level and pattern of wealth holdings. There are also distinct differences at the regional level. It is therefore interesting to compare regional variations and trends since the year 2000, and to document the variety of country circumstances and experiences.

While data quality is generally good in the rich countries that hold most of the world's wealth, it is usually questionable elsewhere. The countries discussed in this section are all interesting in their own right. But another reason for their selection is that they all have data on the mean level of household wealth and a reasonable way to estimate the distribution of wealth across the population.

The accompanying tables collate information on wealth holdings for each of the regions and countries. Some of the core data is summarized in Table 6-1. Table 6-2 reports wealth per adult measured in current US dollars and in "constant dollars" by which is meant the average USD exchange rate for the period 2010-2016. Table 6-3 provides similar information for aggregate household wealth measured in trillion US dollars. Table 6-4 shows the composition of wealth for the most recent year for which figures are available. For each region and country, the wealth share of each decile and the top percentiles is recorded in Table 6-5, along with the minimum wealth needed to belong to a given regional wealth quantile. Finally, Table 6-6 shows the distribution of the adult population by wealth range.

### 6.2 Mean wealth 2000–2016

Three charts are provided for each of the regions. Figure 1 plots two series for mean wealth over 2000–2016, one measured in current US dollars and the second calculated using the average USD exchange rate. The global level of wealth per adult – which amounted to USD 52,800 in 2016 – masks considerable regional variation. The average for North America in 2016 was USD 337,100 compared to USD 125,500 in Europe, USD 46,300 in the Asia-Pacific region (excluding China and India), USD 18,400 in Latin America, USD 22,900 in China, USD 4,300 in Africa and USD 3,800 in India.

All regions have recorded an increase in wealth per adult since the start of the century. If wealth is measured in local currencies, growth has been sustained and generally continuous apart from the financial crisis period when all regions except Latin America suffered a setback. If wealth is valued in current USD, the picture is somewhat different. Between 2000 and 2007, dollar depreciation raises the regional growth rates; but dollar appreciation in more recent years has had the opposite effect. As a consequence, wealth per adult in 2016 is at or below its 2007 level in every region except Asia-Pacific, North America and China.

This in turn has implications for global wealth inequality. Although wealth levels in Europe and Northern America have always been far above those in other regions, particularly Africa and India, the regional imbalance appeared to be eroding during the early years of the century. Africa, India, Latin America, and most notably China, all increased their share of world wealth between 2000 and 2007, hinting at the possibility that global wealth inequality was on a long-term downward trend. The subsequent reversal of growth rates accompanied by evidence of growing wealth inequality both within and between countries suggests that falling wealth inequality may be a more distant prospect.

### 6.3 Components of personal wealth

Table 6-4 displays the breakdown of wealth per adult for each region into financial and real (non-financial) forms, as well as the average level of debt. On average internationally, financial assets now comprise 55% of gross assets, while non-financial assets account for 46% and debts amount to 14%. Financial assets are relatively more important in Japan where they represent 60% of gross assets and the United States, where they account for 72%. In developing regions, non-financial assets typically account for the bulk of household wealth: they form 71% of gross assets in Latin America and 86% of assets in India, for example.

A systematic link with the stage of development is also evident in the level of household debts expressed as a percentage of gross assets. The share is 9% in India, 8% in China and 10% in Africa, but averages 15% in the Asia-Pacific region, Europe and North America.

### 6.4 Wealth distribution

Table 6-5 shows wealth distribution for each region. Some interesting contrasts between regions are evident. More than 93% of adults in Africa own less than USD 10,000, and 96% of adults in India fall in this range. Meanwhile the fraction is 68% in China, 49% in Europe and 34% in North America. On the other hand, 25% of adults in Europe and 38% in North America have wealth above USD 100,000. The wealth distribution in both Latin America and the Asia-Pacific region closely resembles the pattern in the world as a whole, and Latin America shows 70% and Asia-Pacific 75% of all adults owning less than USD 10,000.

Among developed countries, there is substantial variation in the percentage of adults recorded in the lowest wealth ranges. Some countries report significant numbers of people in this category, while others show very few. This reflects such factors as availability of credit including student loans, as well as how many young adults live separately from their parents, making their low wealth more apparent in the survey returns.

## About the authors

**Anthony Shorrocks** is Director of Global Economic Perspectives Ltd. After receiving his PhD from the London School of Economics (LSE), he taught at the LSE until 1983, when he became Professor of Economics at Essex University, serving also as Head of Department and Director of Economic Research for the British Household Panel Study. In 2001, he was appointed Director of the World Institute for Development Economics Research of the United Nations University (UNUWIDER) in Helsinki, where he remained until 2009. He has published widely on income and wealth distribution, inequality, poverty and mobility, and was elected a Fellow of the Econometric Society in 1996. Publications include "The age-wealth relationship: A cross section and cohort analysis" (Review of Economics and Statistics 1975), "The portfolio composition of asset holdings in the United Kingdom" (Economic Journal 1982), and, with Jim Davies and others, "Assessing the quantitative importance of inheritance in the distribution of wealth" (Oxford Economic Papers 1978), "The distribution of wealth" (Handbook of Income Distribution 2000), "The world distribution of household wealth" in Personal Wealth from a Global Perspective (Oxford University Press 2008), "The global pattern of household wealth" (Journal of International Development 2009) and "The Level and Distribution of Global Household Wealth" (Economic Journal 2011).

**Jim Davies** is a Professor in the Department of Economics at the University of Western Ontario in Canada, where he has been a faculty member since 1977 and served as chair of the department from 1992 to 2001. He received his PhD from the London School of Economics in 1979. Jim was the director of the Economic Policy Research Institute at UWO from 2001 to 2012. In 2010, he completed a five-year term as managing editor of the academic journal Canadian Public Policy. From 2006 to 2008, he directed an international research program on household wealth holdings at UNU-WIDER in Helsinki and edited the resulting volume, "Personal Wealth from a Global Perspective" (Oxford University Press 2008). He has authored two books and over 70 articles and chapters in books on topics ranging from tax policy to household saving and the distribution of wealth. Publications include "The Relative Impact of Inheritance and Other Factors on Economic Inequality" (Quarterly Journal of Economics 1982), "Wealth and Economic Inequality" (Oxford Handbook of Economic Inequality, Oxford University Press, 2009), and several publications on wealth authored jointly with Anthony Shorrocks and others. Jim is also the editor of "The Economics of the Distribution of Wealth," published in 2013 by Edward Elgar.

**Rodrigo Lluberás** is an Analyst at the Research department of Uruguay Central Bank. He received his PhD in Economics from Royal Holloway College, University of London and his MSc in Economics from University College London. He has been a visiting scholar at the Institute for Fiscal Studies and an Economist at Towers Watson in London. Prior to undertaking his MSc, he worked for three years as an economic analyst at Watson Wyatt Global Research Services and more recently as a research assistant at NESTA. His main areas of expertise are pensions, consumption and wealth.

## General disclaimer / Important information

This document was produced by and the opinions expressed are those of Credit Suisse as of the date of writing and are subject to change. It has been prepared solely for information purposes and for the use of the recipient. It does not constitute an offer or an invitation by or on behalf of Credit Suisse to any person to buy or sell any security. Nothing in this material constitutes investment, legal, accounting or tax advice, or a representation that any investment or strategy is suitable or appropriate to your individual circumstances, or otherwise constitutes a personal recommendation to you. The price and value of investments mentioned and any income that might accrue may fluctuate and may fall or rise. Any reference to past performance is not a guide to the future.

The information and analysis contained in this publication have been compiled or arrived at from sources believed to be reliable but Credit Suisse does not make any representation as to their accuracy or completeness and does not accept liability for any loss arising from the use hereof. A Credit Suisse Group company may have acted upon the information and analysis contained in this publication before being made available to clients of Credit Suisse. Investments in emerging markets are speculative and considerably more volatile than investments in established markets. Some of the main risks are political risks, economic risks, credit risks, currency risks and market risks. Investments in foreign currencies are subject to exchange rate fluctuations. Any questions about topics raised in this piece or your investments should be made directly to your local relationship manager or other advisers. Before entering into any transaction, you should consider the suitability of the transaction to your particular circumstances and independently review (with your professional advisers as necessary) the specific financial risks as well as legal, regulatory, credit, tax and accounting consequences. This document is issued and distributed in the United States by Credit Suisse Securities (USA) LLC, a U.S. registered broker-dealer; in Canada by Credit Suisse Securities (Canada), Inc.; and in Brazil by Banco de Investimentos Credit Suisse (Brasil) S.A.

This document is distributed in Switzerland by Credit Suisse AG, a Swiss bank. Credit Suisse is authorized and regulated by the Swiss Financial Market Supervisory Authority (FINMA). This document is issued and distributed in Europe (except Switzerland) by Credit Suisse (UK) Limited and Credit Suisse Securities (Europe) Limited. Credit Suisse Securities (Europe) Limited and Credit Suisse (UK) Limited, both authorized by the Prudential Regulation Authority and regulated by the Financial Conduct Authority and the Prudential Regulation Authority, are associated but independent legal entities within Credit Suisse. The protections made available by the Financial Conduct Authority and/or the Prudential Regulation Authority for retail clients do not apply to investments or services provided by a person outside the UK, nor will the Financial Services Compensation Scheme be available if the issuer of the investment fails to meet its obligations. To the extent communicated in the United Kingdom ("UK") or capable of having an effect in the UK, this document constitutes a financial promotion which has been approved by Credit Suisse (UK) Limited which is authorized by the Prudential Regulation Authority and regulated by the Financial Conduct Authority and the Prudential Regulation Authority for the conduct of investment business in the UK. The registered address of Credit Suisse (UK) Limited is Five Cabot Square, London, E14 4QR. Please note that the rules under the UK's Financial Services and Markets Act 2000 relating to the protection of retail clients will not be applicable to you and that any potential compensation made available to "eligible claimants" under the UK's Financial Services Compensation Scheme will also not be available to you. Tax treatment depends on the individual circumstances of each client and may be subject to changes in future. This document is distributed in Guernsey by Credit Suisse (Channel Islands) Limited, an independent legal entity registered in Guernsey under 15197, with its registered address at Helvetia Court, Les Echelons, South Esplanade, St Peter Port, Guernsey. Credit Suisse (Channel Islands) Limited is wholly owned by Credit Suisse AG and is regulated by the Guernsey Financial Services Commission. Copies of the latest audited accounts are available on request. This document is distributed in Jersey by Credit Suisse (Channel Islands) Limited, Jersey Branch, which is regulated by the Jersey Financial Services Commission for the conduct of investment business. The address of Credit Suisse (Channel Islands) Limited, Jersey Branch, in Jersey is: TradeWind House, 22 Esplanade, St Helier, Jersey JE4 5WU. This document has been issued in Asia-Pacific by whichever of the following is the appropriately authorised entity of the relevant jurisdiction: in Hong Kong by Credit Suisse (Hong Kong) Limited, a corporation licensed with the Hong Kong Securities and Futures Commission or Credit Suisse Hong Kong branch, an Authorized Institution regulated by the Hong Kong Monetary Authority and a Registered Institution regulated by the Securities and Futures Ordinance (Chapter 571 of the Laws of Hong Kong); in Japan by Credit Suisse Securities (Japan) Limited; this document has been prepared and issued for distribution in Singapore to institutional investors, accredited investors and expert investors (each as defined under the Financial Advisers Regulations) only, and is also distributed by Credit Suisse AG, Singapore Branch to overseas investors (as defined under the Financial Advisers Regulations). Credit Suisse AG, Singapore Branch may distribute reports produced by its foreign entities or affiliates pursuant to an arrangement under Regulation 32C of the Financial Advisers Regulations. Singapore recipients should contact Credit Suisse AG, Singapore Branch at +65-6212-2000 for matters arising from, or in connection with, this report. By virtue of your status as an institutional investor, accredited investor, expert investor or overseas investor, Credit Suisse AG, Singapore Branch is exempted from complying with certain compliance requirements under the Financial Advisers Act, Chapter 110 of Singapore (the "FAA"), the Financial Advisers Regulations and the relevant Notices and Guidelines issued thereunder, in respect of any financial advisory service which Credit Suisse AG, Singapore branch may provide to you. ; elsewhere in Asia/Pacific by whichever of the following is the appropriately authorized entity in the relevant jurisdiction: Credit Suisse Equities (Australia) Limited, Credit Suisse Securities (Thailand) Limited, Credit Suisse Securities (Malaysia) Sdn Bhd, Credit Suisse AG, Singapore Branch, and elsewhere in the world by the relevant authorized affiliate of the above.
